

# Package ‘polyBreedR’

December 24, 2025

**Title** Genomics-assisted breeding for polyploids (and diploids)

**Version** 0.50

**Author** Jeffrey B. Endelman

**Maintainer** Jeffrey Endelman <endelman@wisc.edu>

**Description** Genomics-assisted breeding for polyploids (and diploids)

**Depends** R (>= 4.0)

**License** GPL-3

**LazyData** true

**RoxygenNote** 7.3.2

**Encoding** UTF-8

**Imports** AGHmatrix, ggplot2, ggrepel, pedigree, grDevices, utils, tidyverse, Matrix, rlang, updog, randomForest, vcfR, rrBLUP, data.table

**Suggests** knitr, rmarkdown

**VignetteBuilder** knitr

<b>ADsplit</b>	<i>Extract read counts from AD string</i>
----------------	---

---

### Description

Extract read counts from AD string

### Usage

```
ADsplit(AD, ALT, n.core = 1)
```

### Arguments

AD	array of AD strings
ALT	TRUE or FALSE (= REF)
n.core	number of cores

### Details

Only valid for a single ALT allele.

### Value

integer data with same dimensions as AD

---

<b>array2vcf</b>	<i>SNP array to VCF</i>
------------------	-------------------------

---

### Description

Converts output from Genome Studio (Final Report or Wide) to VCF

### Usage

```
array2vcf(array.file, map.file, model.file = NULL, ploidy, vcf.file)
```

### Arguments

array.file	name of input file with SNP array allele intensities
map.file	vcf file with map positions for the markers
model.file	normal mixture model parameters for genotype calls
ploidy	sample ploidy, for use with model.file
vcf.file	output vcf file

**Details**

Auto-detects whether the input file is a Genome Studio Final Report, which is a "long" format with 9-row header, or in "wide" format, where all the data for each marker is one row. XY values are multiplied by 100

Genotype calls will attempt to be imported from the GS Final Report when `model.file=NULL`. For diploids, columns named "Allele 1 - AB" and "Allele 2 - AB" are expected. For tetraploids, a single column named "Alleles - AB" is expected.

It is assumed that the parameters in `model.file` lead to genotype calls for the dosage of allele B. For a VCF file, genotype calls need to be based on the dosage of ALT. By default, it is assumed that A is the REF allele. For variants where B is REF, include "REF=B" as INFO in the VCF `map.file`.

---

**A\_mat***Additive relationship matrix from pedigree*

---

**Description**

Additive relationship matrix from pedigree

**Usage**

```
A_mat(ped, ploidy, order.ped = TRUE)
```

**Arguments**

<code>ped</code>	Pedigree in three column format: id, mother, father
<code>ploidy</code>	2 or 4
<code>order.ped</code>	TRUE/FALSE does the pedigree need to be ordered so that progeny follow parents

**Details**

This is a wrapper that prepares the pedigree in the format required for R package `AGHmatrix` by Amadeu et al. (2016) (cite them if you use this function). A random bivalents model for tetraploid meiosis is assumed.

**Value**

Additive relationship matrix (dim: indiv x indiv)

**References**

Amadeu et al. (2016) Plant Genome 9, doi:10.3835/plantgenome2016.01.0009

**check\_ploidy** *Check ploidy for tetraploids*

### Description

Fraction of simplex or triplex markers

### Usage

```
check_ploidy(geno = NULL, map = NULL, vcf.file = NULL, max.missing = 0.1)
```

### Arguments

geno	Genotype matrix (markers x indiv)
map	Data frame with marker map (Marker, Chrom, Position)
vcf.file	VCF file input
max.missing	maximum proportion of missing data allowed per marker

### Details

For every indiv in the genotype matrix, the fraction of markers per chromosome called as simplex or triplex is calculated, which should be low for diploids. A small amount of missing genotype data can be tolerated.

As of v4.2, a VCF file can be used as input instead

### Value

List containing

**mat** Matrix (indiv x chrom) of results

**plot** ggplot2 barplot

**check\_trio** *Check markers for parent-offspring trio*

### Description

Check markers for parent-offspring trio

### Usage

```
check_trio(parentage, geno, ploidy)
```

### Arguments

parentage	Data frame with three columns: id, mother, father
geno	Matrix of allele dosages: markers x indiv
ploidy	2 or 4

**Details**

Computes the percentage of markers at which the two parents and offspring have incompatible allele dosages (for tetraploids, the random bivalents model is used). For dihaploid offspring of a single tetraploid parent, use ploidy = 4 and "haploid" for the father in parentage, as well as a diploid (0,1,2) genotype for the offspring. A small amount of missing genotype data can be tolerated.

**Value**

Data frame with the percentage of incompatible markers for each trio

---

contribution	<i>Genetic contribution</i>
--------------	-----------------------------

---

**Description**

Computes genetic contribution from pedigree

Argument ped is three column pedigree; can be created using [get\\_pedigree](#).

**Usage**

```
contribution(id, ped)
```

**Arguments**

id	vector of target names
ped	pedigree

**Value**

matrix of contributions, with rows id and columns for all members of ped

---

dart2vcf	<i>Convert DArTag to VCF</i>
----------	------------------------------

---

**Description**

Convert DArTag to VCF

**Usage**

```
dart2vcf(counts.file, dosage.file, vcf.file, ploidy, first.data.row = 9)
```

**Arguments**

counts.file	DArTag collapsed counts file
dosage.file	DArTag dosage file
vcf.file	name of VCF output file
ploidy	ploidy
first.data.row	default is 9 for DArTag format

## Details

Two input files expected. `counts.file` is the two-row collapsed counts file, whereas `dosage.file` has one row per target, with chrom and position in columns 4 and 5. DArT reports dosage of REF, whereas VCF standard is based on dosage of ALT. The dosage is exported as GT field in VCF.

Duplicate samples are renamed by appending the "Target ID".

`gbs`

*Genotype calls for GBS*

## Description

Genotype calls for genotype-by-sequencing (GBS) data

## Usage

```
gbs(
  in.file,
  out.file,
  ploidy,
  bias = TRUE,
  n.core = 1,
  chunk.size = 1000,
  silent = FALSE,
  model.fit = TRUE
)
```

## Arguments

<code>in.file</code>	VCF input file
<code>out.file</code>	VCF output file
<code>ploidy</code>	ploidy
<code>bias</code>	TRUE/FALSE, whether to estimate allelic bias
<code>n.core</code>	number of cores
<code>chunk.size</code>	number of variants to process at a time
<code>silent</code>	TRUE/FALSE
<code>model.fit</code>	TRUE/FALSE

## Details

VCF input file must contain AD field. Variants with more than 2 alleles are coerced to zero DP, so better to filter them out first.

Posterior mode and mean genotypes are added as GT and DS fields. GQ is also added based on probability of posterior mode. Binomial calculation uses R/updog package (Gerard et al. 2018) with "norm" prior. Previous INFO is discarded; adds NS, DP.AVG, AF.GT, AB, OD, SE.

When `model.fit` is FALSE, the software uses AB, OD, and SE parameters from INFO.

The input file is processed in chunks of size `chunk.size`.

## Value

`nothing`

---

geno_call	<i>Genotype calls</i>
-----------	-----------------------

---

## Description

Genotype calls based on a normal mixture model

## Usage

```
geno_call(  
  data,  
  filename,  
  model.ploidy = 4L,  
  sample.ploidy = 4L,  
  min.posterior = 0,  
  transform = TRUE  
)
```

## Arguments

data	matrix (markers x id) of input values for the normal mixture model
filename	CSV filename with the model parameters
model.ploidy	2 or 4 (default)
sample.ploidy	2 or 4 (default)
min.posterior	minimum posterior probability (default 0) for genotype call
transform	TRUE (default) or FALSE whether to apply arcsin square root transformation

## Details

The first column of the CSV input file should be the SNP ID, followed by columns for the normal distribution means, standard deviations, and mixture probabilities. Genotype calls are based on the maximum a posteriori (MAP) method. If the posterior probability of the MAP genotype is less than `min.posterior`, then NA is returned for that sample. By default, an arcsin square root transformation is applied to the input values to match the approach used by R package `fitPoly`. To use a tetraploid mixture model for diploid samples, set `sample.ploidy = 2` and `model.ploidy = 4`.

## Value

matrix of allele dosages (0,1,2,...ploidy) with dimensions markers x individuals

<code>get_parents</code>	<i>Get parents of genotypes</i>
--------------------------	---------------------------------

### Description

Get parents of genotypes

### Usage

```
get_parents(id, pedfile, delim = ",", na.string = "NA", DH = FALSE)
```

### Arguments

<code>id</code>	Vector of target names
<code>pedfile</code>	Name of pedigree file
<code>delim</code>	Delimiter for the pedigree file (default is "," for CSV)
<code>na.string</code>	String used for NA in the pedigree file (default is "NA")
<code>DH</code>	TRUE/FALSE should 4x parent of dihaploid be returned

### Details

The function generates data frame with the parents of the input `id`. For lines with any degree of inbreeding (more than one en-dash) or dihaploids (-DH), no look-up table is needed. Otherwise, the parents are searched in the three-column `pedfile` (`id,mother,father`), The `id` column can be the identifier for an individual or cross. String matches must be exact or based on the naming convention `crossID-progenyID`.

### Value

Data frame with columns `id`, `mother`, `father`

<code>get_pedigree</code>	<i>Generate pedigree</i>
---------------------------	--------------------------

### Description

Generate pedigree for A matrix calculation

### Usage

```
get_pedigree(
  id,
  pedfile,
  delim = ",",
  na.string = "NA",
  trim = TRUE,
  founders = F,
  DH = F
)
```

**Arguments**

<code>id</code>	Vector of genotype names
<code>pedfile</code>	Name of pedigree file
<code>delim</code>	Delimiter for the pedigree file (default is "," for CSV)
<code>na.string</code>	String used for NA in the pedigree file (default is "NA")
<code>trim</code>	TRUE/FALSE whether to trim pedigree (see Details)
<code>founders</code>	TRUE/FALSE should all pedigree founders be included in id column
<code>DH</code>	TRUE/FALSE should 4x parent of dihaploids be included

**Details**

Returns ancestors of `id` using lower-level function `get_parents`. Input `pedfile` is three-column pedigree file (`id,mother,father`). The `id` column can be the identifier for an individual or cross. String matches must be exact or based on the naming convention `crossID-progenyID`. As of v0.48, inbred line names are supported, with en-dash separating each generation of inbreeding.

The returned pedigree is ordered using R package `pedigree` so that offspring follow parents. When `trim` is TRUE (default), the pedigree is trimmed to remove ancestors with only one offspring (which are not needed to compute the pedigree relationship matrix).

**Value**

Data frame with columns `id`, `mother`, `father`

GT2DS

*Convert GT to ALT allele dosage (DS)***Description**

Convert GT to ALT allele dosage (DS)

**Usage**

```
GT2DS(GT, diploidize = FALSE, n.core = 1)
```

**Arguments**

<code>GT</code>	GT string
<code>diploidize</code>	TRUE/FALSE
<code>n.core</code>	number of cores

**Details**

If `diploidize` is TRUE, data are recoded as a diploid (0,1,2).

**Value**

integer data with same dimensions as `GT`

GvsA

*Plot G vs. A***Description**

Plot marker-based vs. pedigree-based additive relationship coefficients

**Usage**

```
GvsA(
  parentage,
  G,
  A,
  filename = NULL,
  thresh.G = Inf,
  thresh.A = 0.5,
  Gmax = NULL,
  Amax = NULL
)
```

**Arguments**

parentage	Data frame of individuals to plot, with 3 columns: id,mother,father
G	Genomic relationship matrix
A	Pedigree relationship matrix
filename	Name of PDF file to save the results (optional for one individual)
thresh.G	Threshold above which names are displayed (default Inf)
thresh.A	Threshold above which names are displayed (default 0.5)
Gmax	Upper limit for y-axis for plotting. If NULL, maximum value in G is used.
Amax	Upper limit for x-axis for plotting. If NULL, maximum value in A is used.

**Details**

Useful for finding and correcting pedigree errors. If the G or A coefficient for an individual exceeds the threshold, its name is displayed in the figure. If parentage contains one individual, by default a ggplot2 variable will be returned, but the result can also be written to file. If multiple individuals are present, a filename is required.

G\_mat

*Genomic relationship matrix***Description**

Genomic relationship matrix

**Usage**

```
G_mat(geno, ploidy, p.ref = NULL, method = "VR1", sep = "_", n.core = 1)
```

## Arguments

geno	genotype matrix (markers x id) or filename
ploidy	ploidy
p.ref	optional, reference population frequency for method "VR1"
method	"VR1" or "AM"
sep	character separating id from haplotype for "AM" method
n.core	number of cores, only used with "AM"

## Details

For `method="VR1"`, Method 1 of VanRaden (2008) is used, and its polyploid extension (Endelman et al. 2018). Missing data is replaced with the population mean for each marker. If `p.ref` is `NULL`, the current population is used as the reference population. For "VR1", `geno` is an allele dosage matrix for bi-allelic loci (sites x indiv).

For `method="AM"`, the Allele Matching coefficient is calculated, which is the probability that two haplotypes sampled at random (with replacement) are identical (Weir and Goudet 2017). Missing data are not allowed. For "AM", `geno` is a phased genotype matrix, with alleles coded as positive integers. The name of each column is the id and haplotype concatenated with a separating character, `sep`. This character needs to be unique (i.e., not present in id or haplotype).

## Value

`G` matrix

## References

- VanRaden (2008) J. Dairy Sci 91:4414-4423.  
 Endelman et al. (2018) Genetics 209:77-87.  
 Weir and Goudet (2017) Genetics 206:2085-2103.

`impute`

*Impute missing data for bi-allelic markers*

## Description

Impute missing data for bi-allelic markers

## Usage

```
impute(
  in.file,
  out.file,
  ploidy,
  method,
  geno,
  min.DP = 1,
  max.missing,
  params = NULL,
  n.core = 1
)
```

**Arguments**

<code>in.file</code>	VCF input file
<code>out.file</code>	VCF output file
<code>ploidy</code>	ploidy
<code>method</code>	One of the following: "pop","EM","RF"
<code>geno</code>	One of the following: "GT","DS"
<code>min.DP</code>	genotypes below this depth are set to missing (default=1)
<code>max.missing</code>	remove markers above this threshold, as proportion of population
<code>params</code>	list of method-specific parameters
<code>n.core</code>	multicore processing

**Details**

Assumes input file is sorted by position. Markers with no genetic variance are removed.  
`method="pop"` imputes with the population mean for `geno="DS"` and population mode for `geno="GT"`.  
`method="EM"` uses parameter "tol" (default is 0.02, see rrBLUP A.mat documentation). Imputed values are truncated if needed to fall in the interval [0,ploidy].  
`method="RF"` uses parameters "ntree" (default 100) for number of trees and "nflank" (default 100) for the number of flanking markers (on each side) to use as predictors. Because RF first uses EM to generate a complete dataset, parameter "tol" is also recognized.

**impute\_L2H***Impute from low to high density markers by Random Forest***Description**

Impute from low to high density markers by Random Forest

**Usage**

```
impute_L2H(
  high.file,
  low.file,
  out.file = NULL,
  params = list(),
  exclude = NULL,
  n.core = 1
)
```

**Arguments**

<code>high.file</code>	name of high density file
<code>low.file</code>	name of low density file
<code>out.file</code>	name of CSV output file for imputed data
<code>params</code>	list of parameters (see Details)
<code>exclude</code>	optional, vector of high density samples to exclude
<code>n.core</code>	multicore processing

## Details

Argument `params` is a list with the following options: `format`, `model`, `n.tree`, `n.mark`. `format` can have values "GT" (integer dosage) or "DS" (real numbers between 0 and ploidy). `model` can be "class" for classification or "regress" for regression when "GT" is used; for "DS" format, only regression is permitted. `n.tree` is the number of trees (default = 100). `n.mark` is the number of markers to use as predictors (default = 100), chosen based on minimum distance to the target.

The `exclude` argument is useful for cross-validation.

Both VCF and CSV are allowable input file formats—they are recognized based on the file extension. For CSV, the first three columns should be marker, chrom, pos. The output file is CSV.

Any missing data are imputed separately for each input file at the outset, using the population mean (regress) or mode (class) for each marker.

## Value

matrix of OOB error with dimensions markers x trees. For regression model, it is MSE.

`impute_LA`

*Impute from low to high density markers by Linkage Analysis (LA)*

## Description

Impute from low to high density markers by Linkage Analysis

## Usage

```
impute_LA(ped.file, high.file, low.file, low.format = "GT", out.file)
```

## Arguments

<code>ped.file</code>	pedigree file for progeny
<code>high.file</code>	name of file with phased parental genotypes
<code>low.file</code>	name of VCF file with progeny
<code>low.format</code>	either "GT" (default) or "AD"
<code>out.file</code>	name of CSV output file

## Details

You must have separately installed PolyOrigin and Julia for this function to work.

The high density file contains phased parental genotypes using 0|1 format. The first 3 columns are the genetic map in cM: marker, chrom, position. To output imputed data with physical rather than genetic map positions, including a fourth column named "bp". Subsequent columns are the phased parental genotypes.

VCF is assumed for the low-density file. The pedigree file has four columns: id, pop, mother, father, ploidy.

The output file contains the posterior maximum genotypes.

A temporary directory "tmp" is created to store intermediate files and then deleted.

**madc***Multi-Allelic Haplotype Counts for potato DArTag***Description**

Multi-Allelic Haplotype Counts for potato DArTag

**Usage**

```
madc(madc.file, marker)
```

**Arguments**

<code>madc.file</code>	MADC filename
<code>marker</code>	Name of marker ("CDF1","OFP20","Rychc")

**Details**

Due to multi-allelism, for some trait markers a correct interpretation is not possible using the collapsed counts file; the MADC (Missing Allele Discovery Count) file is needed.

"CDF1" uses marker CDF1.4\_chr05\_4488021 to detect the 2C, 2T, and 4 alleles; all other haplotypes are treated as allele 1. Allele 3 is not detected by the assay.

"OFP20" relies on three markers. Marker OFP20\_M6\_CDS\_994 detects OFP20.1 as Alt and most other haplotypes as Ref, but some alleles appear to be NULL. Marker OFP20\_M6\_CDS\_171 detects allele 2 as Alt and alleles 3 and 7 as Ref; other alleles are NULL. Marker OFP20\_M6\_CDS\_24 detects allele 8 as Ref and most other alleles as Alt. Given the high allelic diversity at this locus, this function may not work in all germplasm groups.

"Rychc" returns read counts at Rychc\_M6v5\_chr09\_37964457 for the M6 allele.

**Value**

matrix of haplotype counts

**maternal\_lineage***Generate pedigree***Description**

Generate pedigree for a set of individuals

**Usage**

```
maternal_lineage(id, pedfile, delim = ",", na.string = "NA")
```

**Arguments**

<code>id</code>	Vector of names of individuals
<code>pedfile</code>	Name of pedigree file
<code>delim</code>	Delimiter for the pedigree file (default is "," for CSV)
<code>na.string</code>	String used for NA in the pedigree file (default is "NA")

## Details

Finds ancestors of individuals in a three-column pedigree file (id,mother,father). The id column can be the identifier for an individual or cross. String matches must be exact or based on the naming convention crossID-progenyID. The returned pedigree is ordered using R package pedigree so that offspring follow parents. When `trim` is TRUE (default), the pedigree is trimmed to remove ancestors with only one offspring (which are not needed to compute the pedigree relationship matrix).

## Value

Data frame with columns id, lineage

---

`merge_impute`

*Merge two genotype matrices and impute missing data (deprecated)*

---

## Description

Merge two genotype matrices and impute missing data by BLUP

## Usage

```
merge_impute(geno1, geno2, ploidy)
```

## Arguments

<code>geno1</code>	Genotype matrix (coded 0...ploidy) with dimensions markers x indiv
<code>geno2</code>	Genotype matrix (coded 0...ploidy) with dimensions markers x indiv
<code>ploidy</code>	Either 2 or 4

## Details

This function is obsolete. Use [impute\\_L2H](#) instead.

Designed to impute from low to high density markers. The BLUP method is equivalent to Eq. 4 of Poland et al. (2012), but this function is not iterative. Additional shrinkage toward the mean is applied if needed to keep the imputed values within the range [0,ploidy]. Missing data in the input matrices are imputed with the population mean for each marker. If an individual appears in both input matrices, it is renamed with suffixes ".1" and ".2" and treated as two different individuals. Monomorphic markers are removed.

## Value

Imputed genotype matrix (markers x indiv)

## References

Poland et al. (2012) Plant Genome 5:103-113.

<code>readXY</code>	<i>Read SNP array intensity data</i>
---------------------	--------------------------------------

## Description

Read SNP array intensity data

## Usage

```
readXY(filename, skip = 9, output = "ratio")
```

## Arguments

<code>filename</code>	filename
<code>skip</code>	number of lines to skip before the header line with the column names
<code>output</code>	One of three options: "ratio","theta","AD"

## Details

The first two columns of the tab-delimited input file should be the SNP and Sample ID. Columns labeled "X" and "Y" contain the signal intensities for the two alleles. Use `output` to specify whether to return the ratio =  $Y/(X+Y)$  or theta =  $\text{atan}(Y/X)*2/\pi$ . Option "AD" exports the XY data in the allele depth format for a VCF file ("X,Y"), with the X and Y values multiplied by 100 and rounded to the nearest integer.

## Value

matrix with dimensions markers x individuals

<code>update_alias</code>	<i>Update names based on alias</i>
---------------------------	------------------------------------

## Description

Update names based on data frame with alias and preferred name

## Usage

```
update_alias(x, alias, remove.space = TRUE, filename = NULL)
```

## Arguments

<code>x</code>	Vector of names to update
<code>alias</code>	Data frame with two columns: first is the preferred name and second is the alias
<code>remove.space</code>	TRUE/FALSE
<code>filename</code>	update names in CSV file

**Details**

Parameter `remove.space` indicates whether blank spaces should be removed before string matching.

**Value**

Vector with updated names

---

`vcf2csv`

*Convert VCF to CSV*

---

**Description**

Convert VCF to CSV

**Usage**

```
vcf2csv(vcf.file, csv.file, format)
```

**Arguments**

<code>vcf.file</code>	Input file
<code>csv.file</code>	Output file
<code>format</code>	Name of FORMAT key to export, either "GT" or "DS"

**Value**

none

---

`write_vcf`

*Create VCFv4.3 file*

---

**Description**

Create VCFv4.3 file

**Usage**

```
write_vcf(filename, fixed, geno, other.meta = NULL)
```

**Arguments**

<code>filename</code>	VCF file name
<code>fixed</code>	character matrix with 8 columns: CHROM, POS, ID, REF, ALT, QUAL, FILTER, INFO
<code>geno</code>	named list of genotype matrices, see Details
<code>other.meta</code>	optional, other metadata (without ##) besides INFO and FORMAT keys

## Details

Several standard INFO key are recognized: ##INFO=<ID=REF,Number=A,Type=Character,Description="Array allele (A/B) in reference genome"> ##INFO=<ID=NS,Number=1,Type=Integer,Description="Number of samples with data"> ##INFO=<ID=DP.AVG,Number=1,Type=Float,Description="Average Sample Depth"> ##INFO=<ID=DP,Number=1,Type=Integer,Description="Total Depth"> ##INFO=<ID=AB,Number=1,Type=Bias"> ##INFO=<ID=SE,Number=1,Type=Integer,Description="Sequencing Error (PHRED)"> ##INFO=<ID=OD,Number=1,Type=Float,Description="Posterior Mean Depth"> ##INFO=<ID=AF,Number=A,Type=Float,Description="Allele Frequency"> ##INFO=<ID=AF.GT,Number=1,Type=String,Description="Allele Frequency based on GT"> ##INFO=<ID=AC,Number=A,Type=Integer,Description="Allele count in genotypes"> ##INFO=<ID=AN,Number=1,Type=Integer,Description="Total number of alleles">" Every element of geno is m x n matrix (m variants, n samples), e.g., AD, GT. The FORMAT field is created from the order and names of geno. Sample names taken from colnames of geno. Metadata for geno is generated from the names of the list: ##FORMAT=<ID=GT,Number=1,Type=String,Description="Genotype"> ##FORMAT=<ID=AD,Number=R,Type=Integer,Description="Allele Depth"> ##FORMAT=<ID=DP,Number=1,Type=Float,Description="Posterior Mean Depth"> ##FORMAT=<ID=DS,Number=1,Type=Float,Description="Posterior Mean Dosage"> ##FORMAT=<ID=GQ,Number=1,Type=Integer,Description="Genotype Quality">

Any additional metadata should be included without the ## prefix.
